

Patient Information:

Name: shivani_7

Gender: Female

Age: 23

Consulting Doctor: Ajinkya SIR

Medical Findings:

Clinical History: A 45-year-old male presents with left lower extremity pain and tenderness after a fall.

Findings: A radiograph of the left tibia was obtained and demonstrates a fracture involving the proximal aspect of the bone. The fracture pattern is characterized as an extra-articular oblique fracture.

Impressions: Further clinical correlation and management are recommended. Orthopedic intervention may be necessary. Consideration for additional imaging studies, such as CT or MRI, to further characterize the fracture pattern and assess soft tissue involvement is advised. Initiation of appropriate pain management and immobilization measures is essential.

Conclusion: The imaging findings demonstrate a proximal extra-articular oblique fracture of the left tibia. Clinical correlation and orthopedic consultation are advised for further management.

Severity:

Moderate
